

OCT in the Diagnosis and Follow-up of Glaucoma

Karim A Raafat MD.

Professor Of Ophthalmology
Cairo University

- Glaucoma suspect.
- Glaucoma workup. → **Damage at presentation**
- Initiate therapy. **Rate of progression.**
- Follow-up. **Progressive change of optic disc or visual field is the hallmark of glaucoma diagnosis.**
- Modify/Change treatment.

“The decision to initiate anti-glaucoma therapy is a *very serious* one that has far-reaching consequences”.

Geroge Spaeth

- Side effects
- Significant cost
- Altered QoL

Rationale for Quantitative Imaging in Glaucoma

- Visual field : subjective , 3 consecutive fields are required to reliably confirm glaucoma.
- **Structural loss precedes functional loss :**
6 years in 60% of eyes.
- As much as **30-50%** of RNFL may be lost before Standard Automated Perimetry (SAP) VF changes.
- Change in the cup represents loss of *thousands of axons.*

**CSLO
HRT**

**SLP
GDx**

OCT-SD

Glaucoma affects **3 areas** in the posterior segment of the eye.

Cupping

Nerve fiber thinning

Ganglion Cell Loss

Peri-papillary RNFL Thickness

ONH Analysis

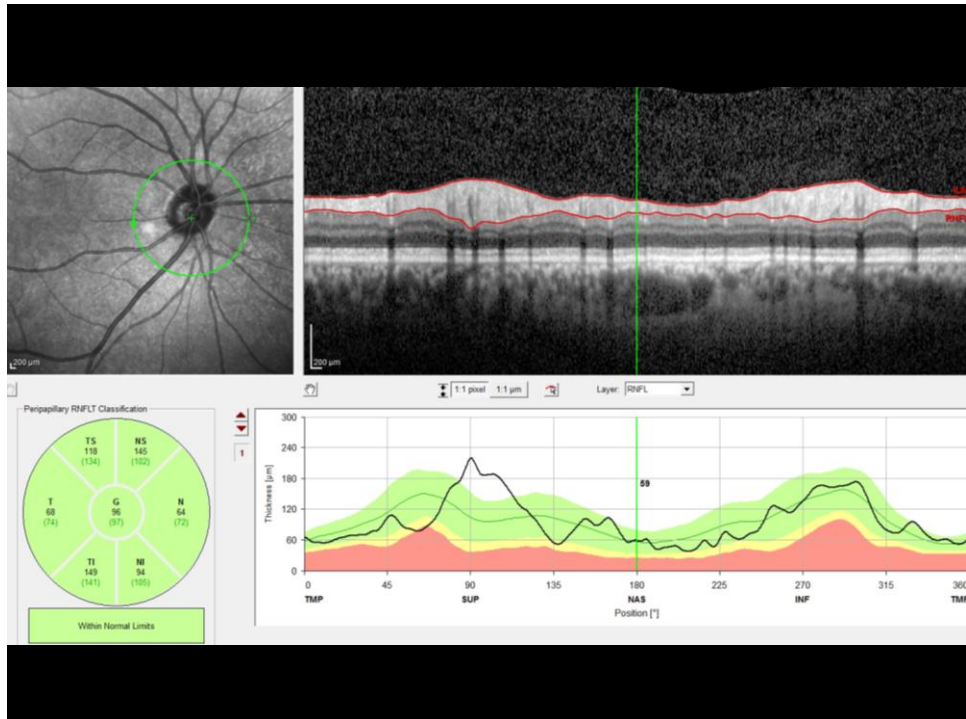

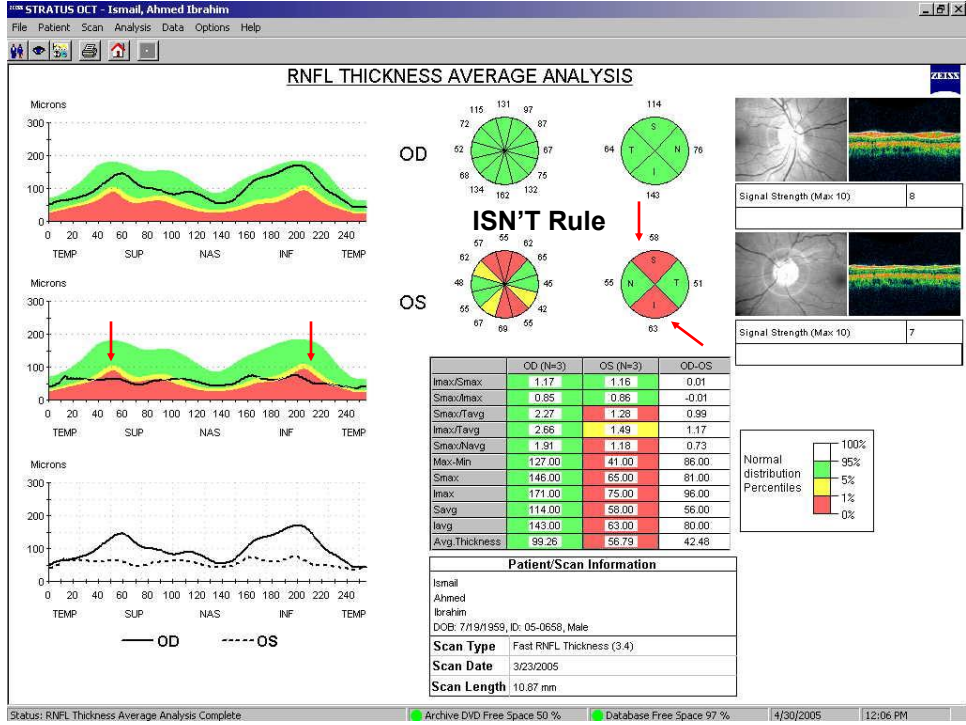

Macular GCC Measurement
SD-OCT

Normal

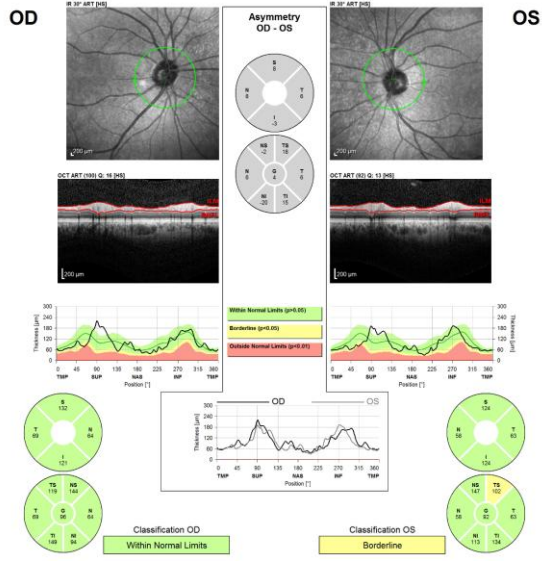

Glaucoma

Boston Diagnostic Eye Center

HEIDELBERG
ENGINEERING

Patient: [redacted] DOB: 05-Oct-1964 Sex: M
Patient ID: 1244 / 12 Exam.: 21-Jul-2012
Diagnosis: --- Comment: ---

“Does any RNFL loss mean Glaucoma ?”

Inferior Average :

- Least affected by age-decay.
- Significantly thinner in glaucoma than in normal.
- Highest sensitivity and specificity in early glaucoma diagnosis.
- Discriminates progressors from non-progressors.

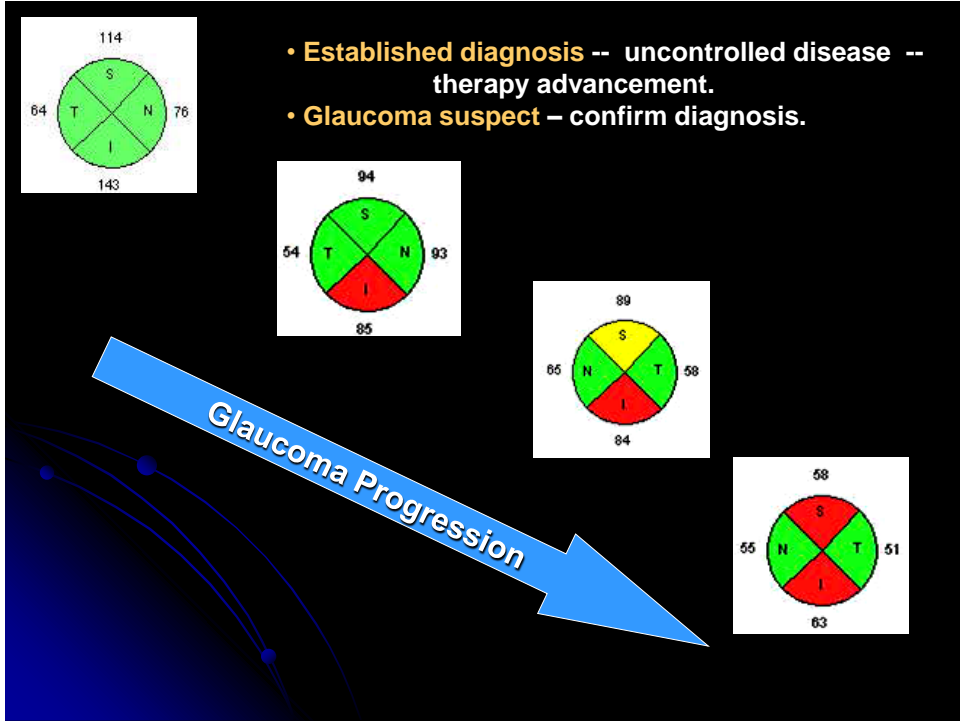

ISN'T Rule

Inferior Average :
 the best to discriminate healthy from glaucomatous eyes

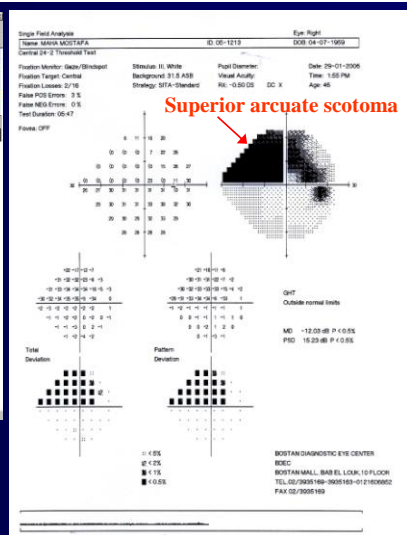

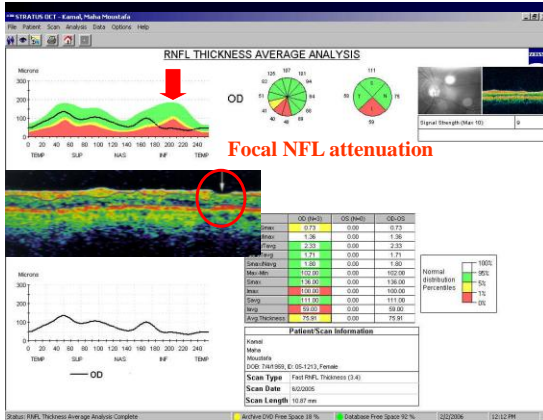

Sensitivity 84%
 Specificity 90%

ISN'T Rule

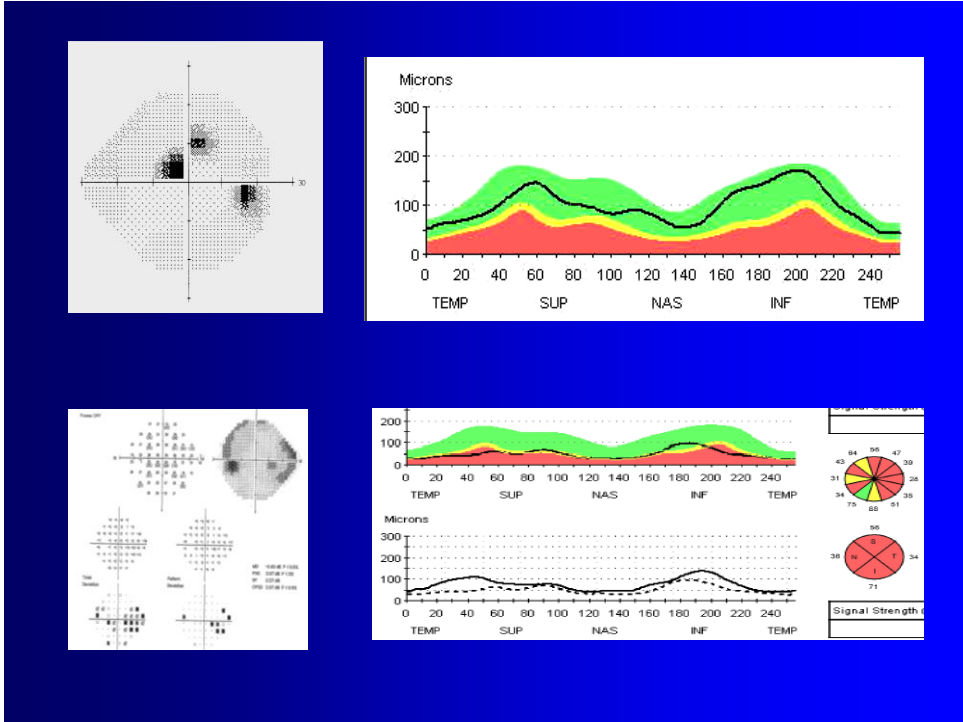

- Established diagnosis -- uncontrolled disease -- therapy advancement.
- Glaucoma suspect – confirm diagnosis.

ISN'T Rule

Perimetric Glaucoma

Glaucoma Visual Field Loss, NO corresponding RNFL Defects.

- 1-clock hour is “*too wide*” for detection of localized loss.

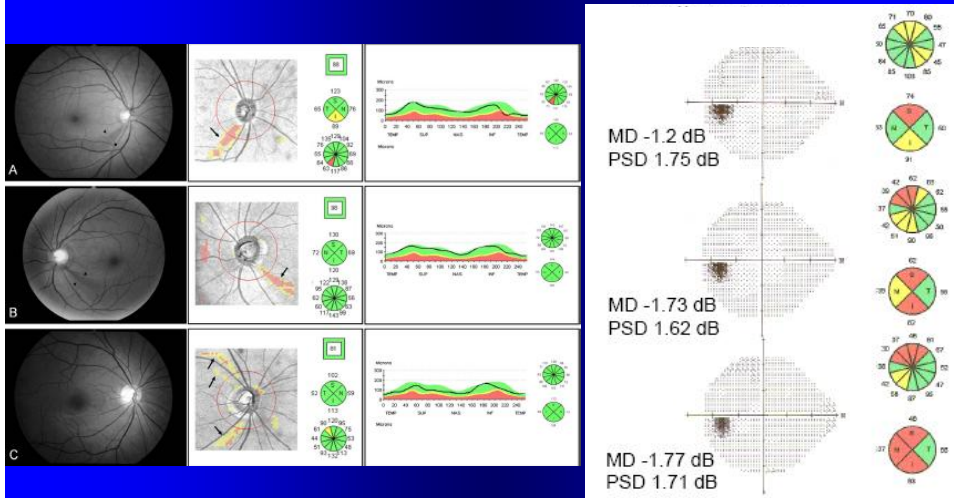

- RNFL defects “*not always*” result in reduction of RNFL thickness.
- Reduction of RNFL thickness not exceed “*normal variation*”.

Glaucoma Visual Field Loss, NO corresponding RNFL Defects.

- Order of Glaucomatous Damage vary from patient to patient.
- Localized RNFL defects limited to deeper layers while most superficial layers being intact.
- Physiologic age-decay of the RNFL.
- Diffuse component of RNFL loss so large to mask localized defects.

Pre-perimetric Glaucoma

Quantitative Imaging may detect glaucoma at an earlier stage.

Jeoung et al , IOVS 2010.

RNFL thickness after IOP reduction

- IOP reduction (medical or surgical) ---- significant increase of mean RNFL thickness .
- Correlated to the IOP reduction
- **0.5 μ increase of mean NFL thickness/ mmHg decrease of IOP**
- Least evident in inferior quadrant

Recovery of the compressed NFL , Retinal swelling , Restoration of normal axoplasmic flow to the RNFL , Changes in the axial length of the globe.

Clinical implication : obtain new OCT measurements as a baseline for follow up after glaucoma surgery .

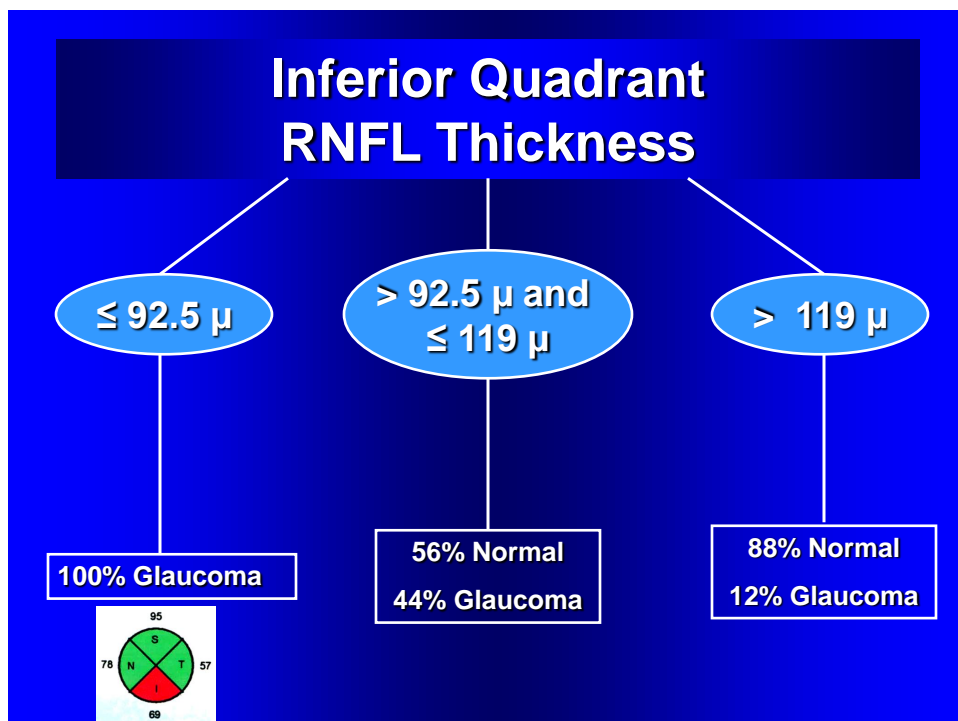

OCT & Early Glaucoma

Moderate Sensitivity and High Specificity

Diagnostic Test

- **Highly specific** : if +ve ----- Rule IN the disease.
- **Highly sensitive** : if -ve ---- Rule OUT the disease.

**OCT (esp inferior RNFL thickness)
rule *IN* early glaucoma when +ve
but can *not* rule *OUT* when -ve**

Advanced Glaucoma

OCT has little role!

Location of 2nd order blood vessels within RNFL

Normal

Focal RNFL loss

Diffuse RNFL loss

Location of 2nd order blood vessels within RNFL

Location of 2nd order blood vessels within RNFL

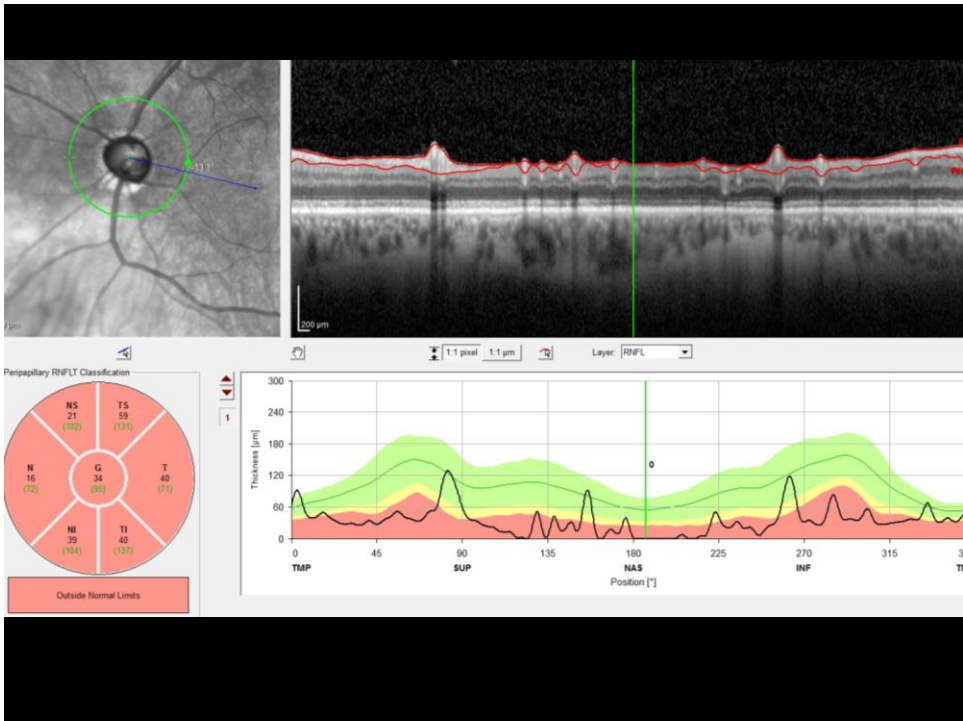

Normal

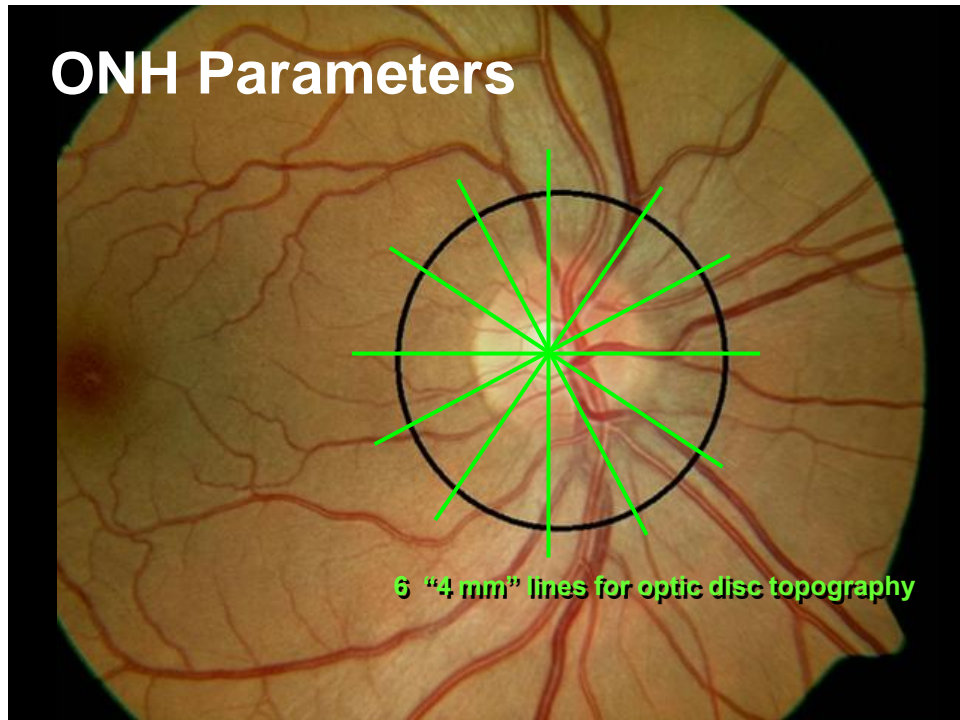

Mild RNFL loss

Severe RNFL loss

TD-OCT

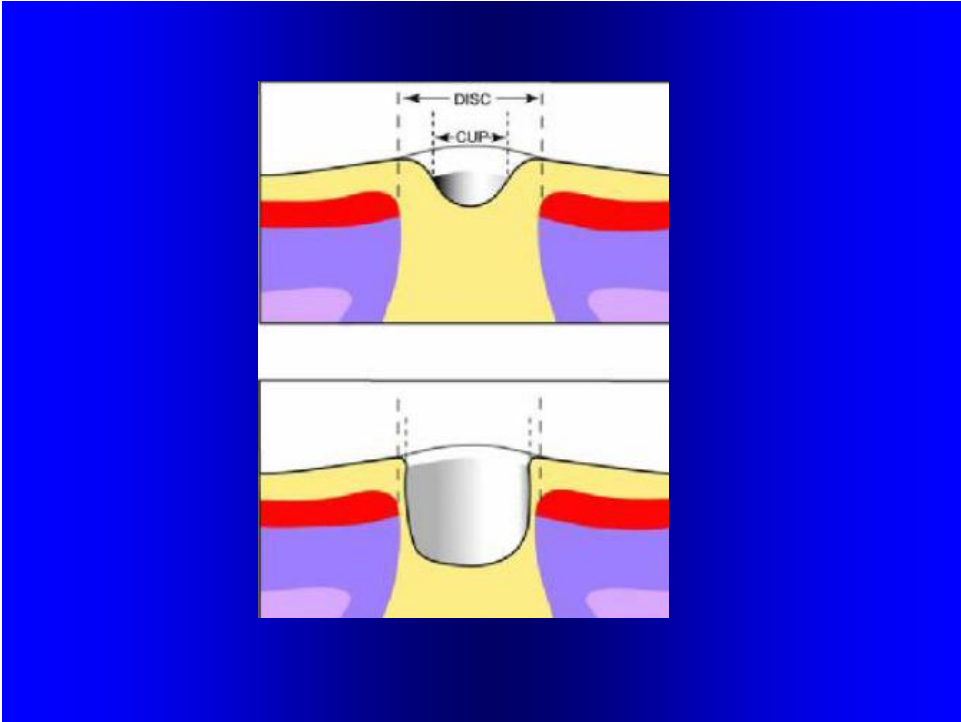

- 3.4 mm circle
- 512 A-scan
- Interpolation : localized RNFL defects can be missed.

SD-OCT

- 6 X 6 mm cube
- 512 X 128 B-scan
- Much higher number of measurements.

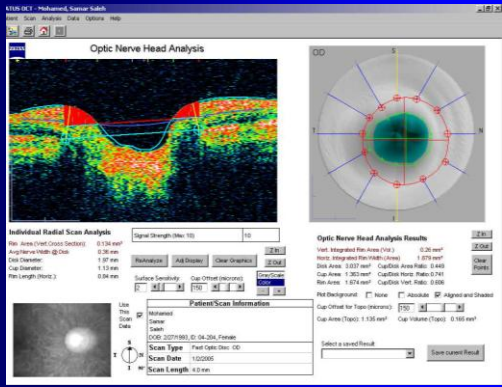

Can not be compared : different tech spcs, imaging protocols and thickness measurement algorithms

ONH Parameters :

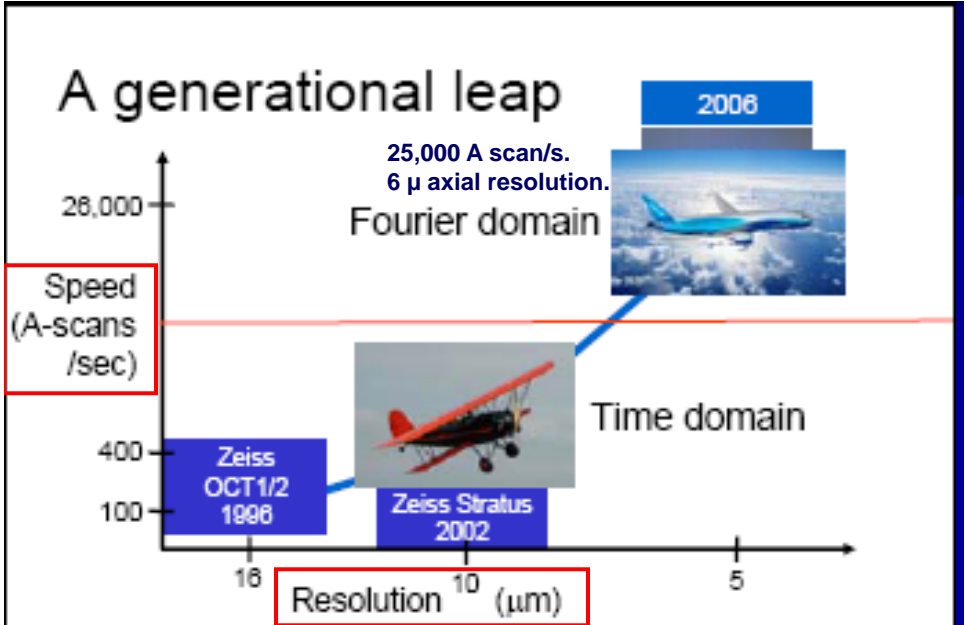

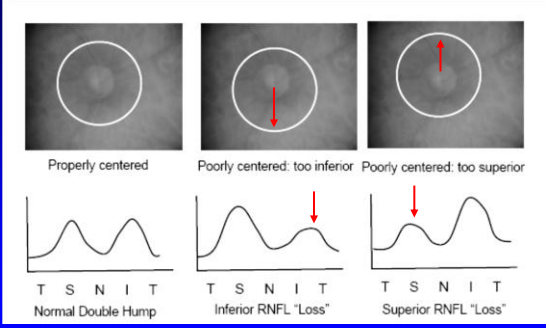

Poor sensitivity for glaucoma progression :

- Interpolation .
- Progressive para papillary atrophy in glaucoma.

TD-OCT susceptible to eye movements – scattering of sampling locations.

Manual placement: scan location affects results.

Higher acquisition speed (X100) , Higher axial resolution (X2)

How to use speed and resolution to advantage?

Microstructure identification

3-D Reconstruction

Function (Blood Flow)

Ganglion Cell Complex (GCC)

- **Axons** : NFL
- **Bodies** : ganglion cell layer
- **Dendrites** : Inner plexiform layer

Glaucoma primarily damages the ganglion cell complex (GCC)

GCC Deviation Map

$$\% \text{ Loss} = \frac{\text{actual} - \text{normal}}{\text{normal}}$$

Blue : 20-30% loss
Black : > 50% loss

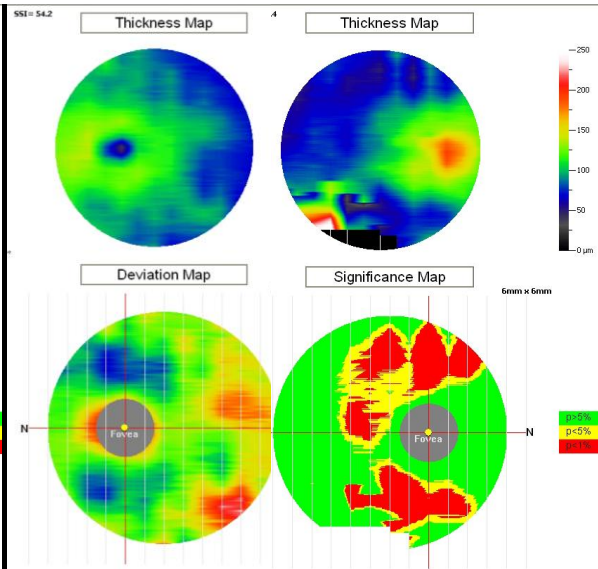

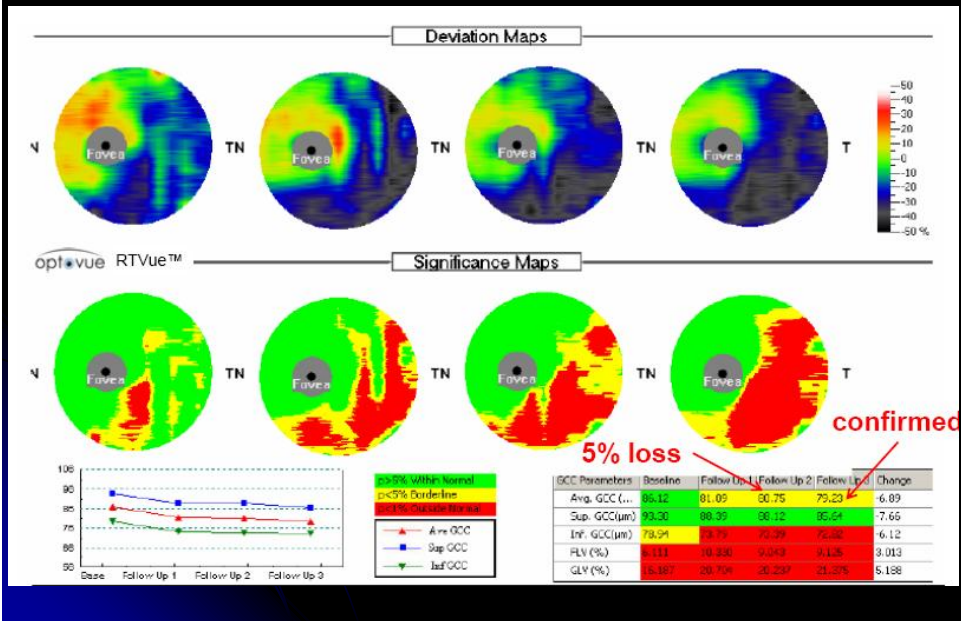

GCC Significance Map

Green : within normal limits.
Yellow : Borderline.
Red : outside normal limits.

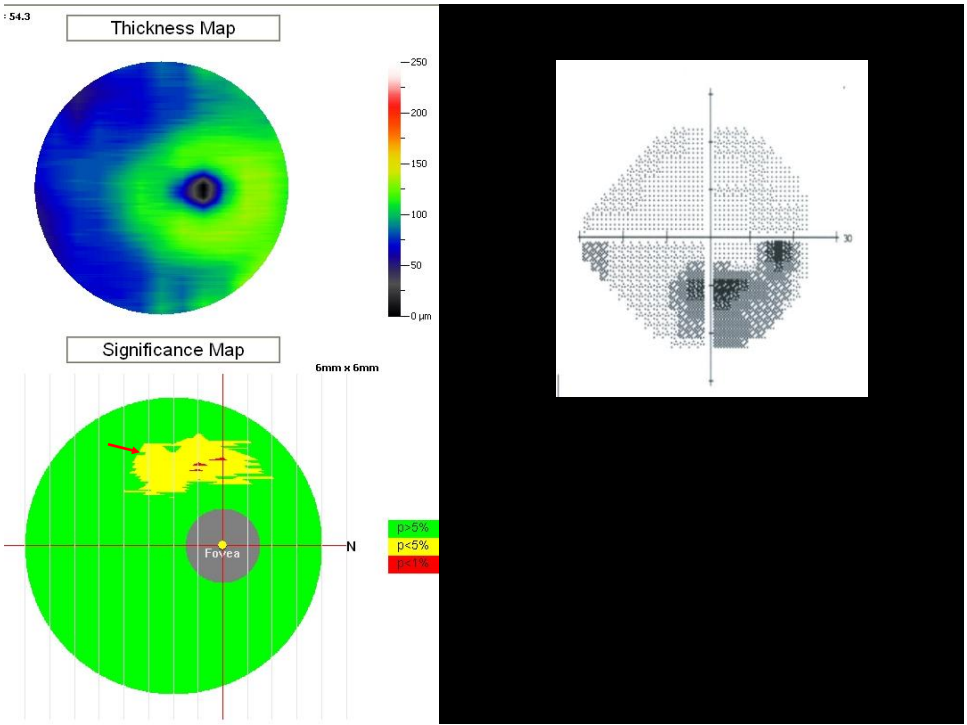

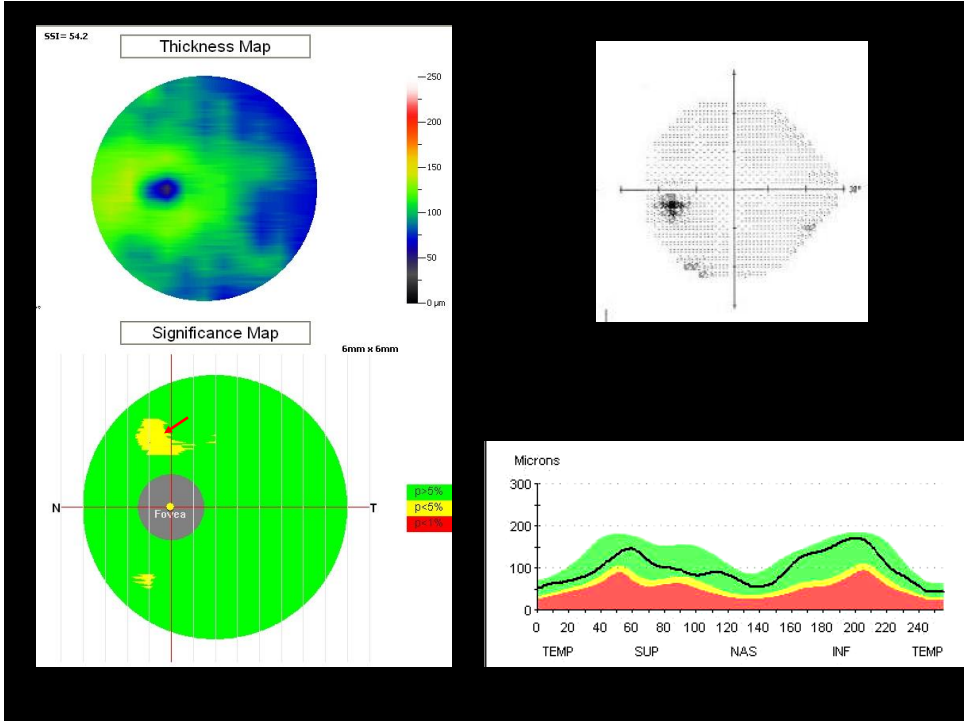

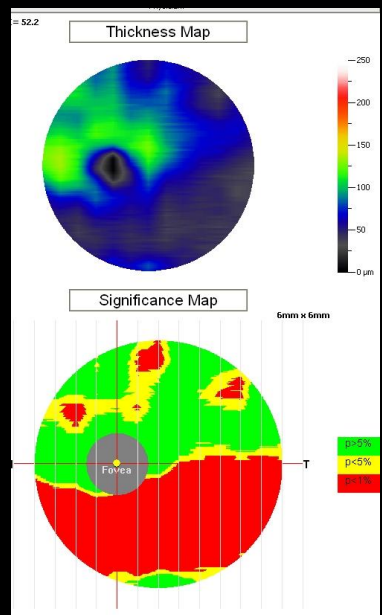

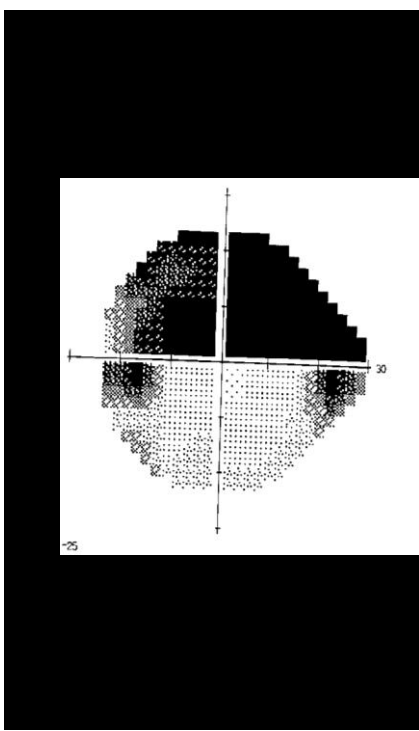

GCC Progression Analysis (visit every 6 months)

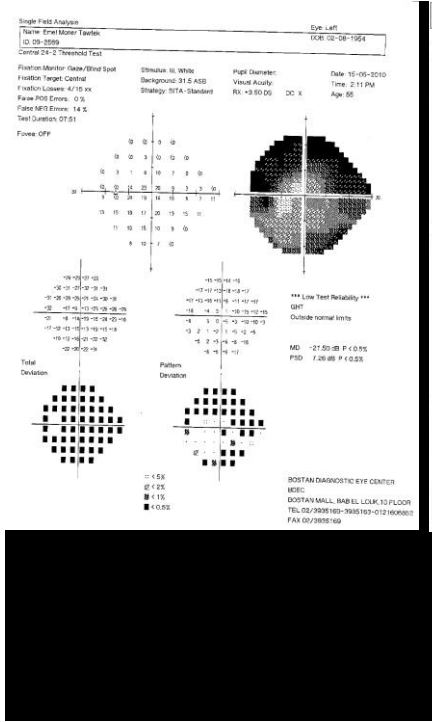

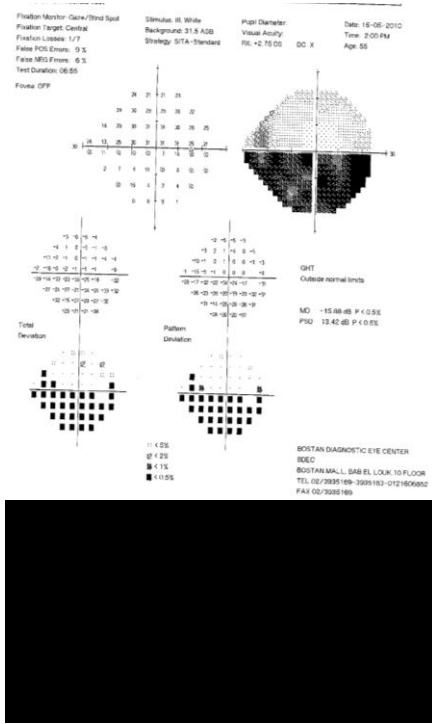

Generalized loss

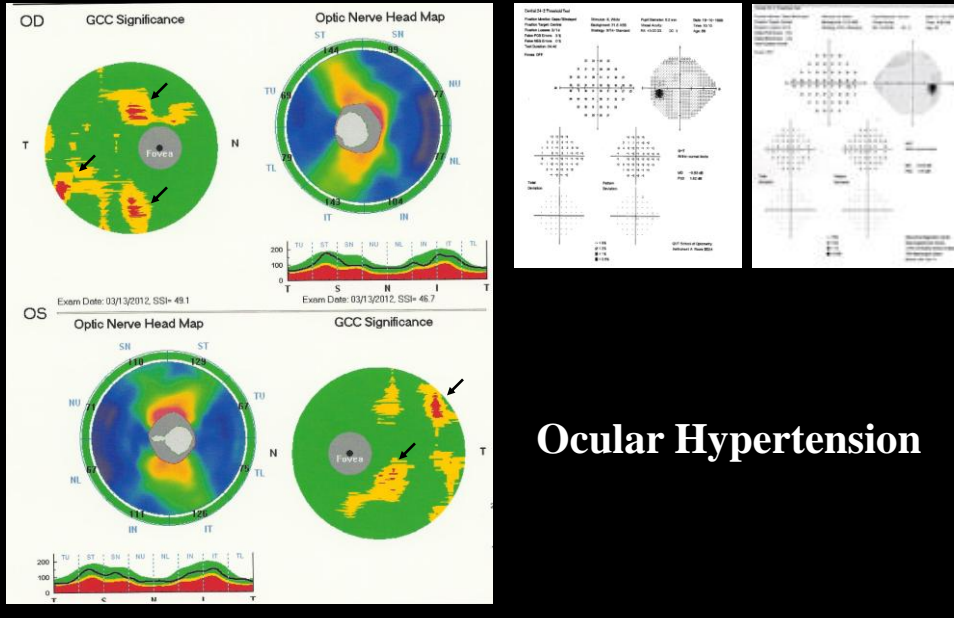

Localized loss

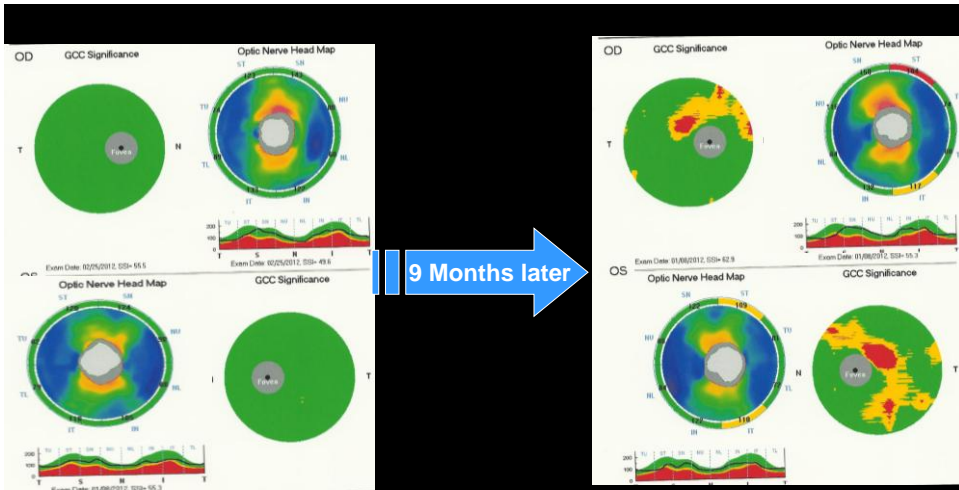

Male , 58 years-old , IOP 27 mmHg (OD) , 26 mmHg (OS)
C/D 0.4 (OD) , 0.3 (OS).

Ocular Hypertension

9 Months later

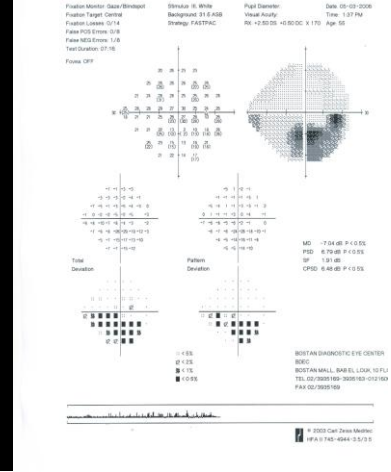

Pre-perimetric Glaucoma

Predict future visual field loss

9 months

Near-future : Doppler OCT measurement of Retinal Blood Flow

Double circular scan

Flow profile and direction determined on parallel sections*

Double circular scan transects all retinal branch vessels 6 times per second

Algorithm for Total Retinal Blood Flow

Y. Wang, et al., Journal of Biomedical Optics 13, 064003, (2008)

Flow in a single vessel

Average flow over 2 seconds for each vessel

Total Retinal Blood Flow \sum Flow in Veins

Flow value : 40.8 to 52.9 μ l/min, CV: 10.5%

Glaucoma reduces retinal blood flow

Group	Number of Subjects	Total retinal blood flow (μl/min)	
		Average	Range
Normal	8	45.64	40.73-52.91
Perimetric Glaucoma	10	33.54 P < 0.003	23.6-40.88
